

# 09-Which fruits are the biggest? An ANOVA example

2023-11-21

## Preface

The following template is intended as a starting point for your analysis. Please follow the general outline (Introduction, Methods, Results, Discussion), but **adapt the content** to your needs. Avoid unnecessary technical details and concentrate on main outcome and its discussion. Include the important (and only the important) tables and graphics and discuss them properly. Special R ideas can also be shown, but long R codes should be avoided.

The intention of the report is to practice an analysis and to get feedback. It can be creative and hopefully also some fun. The following rules apply:

- Maximum 4 students per group,
- The general page limit is: **3 pages** for analyzing the weight data.
- **Two additional pages** allowed if a creative part, e.g. additional data (length, width, weight, ...) are analysed or an additional method is used
- you can also extend the data set by using data from previous years.

## 1 Introduction

Describe briefly the setup of the experiment. Which data sets are to be compared by your group?

What are the Null hypothesis ( $H_0$ ) and the alternative hypothesis ( $H_A$ ) in this experiment?

## 2 Material and Methods

### 2.1 Data

- write something about the data
  - describe the different samples
  - weight determination with a scale, length determination with a caliper (see below)
- read the data in:

```
library(readxl)
library(dplyr)
```

```
brands <- read_excel("clementines_2022.xlsx", "Brands")
fruits <- read_excel("clementines_2022.xlsx", "Fruits")
```

Show the structure of the data. You can also use the `head`-function, shows the first lines of each data set. **Please do not forget to report the sample size of your data!**

```
cat("sample size:", nrow(fruits), "\n")
head(fruits, n=3)
```

```
head(brands, n=3)
```

Join the two tables and convert the Brand column into a factor variable.

```
dat <- left_join(fruits, brands, by="brand")
dat$brand <- factor(dat$brand)
```

## 2.2 Data analysis

Mention R (R Core Team, 2024) in a single sentence, cite special packages. Write that an ANOVA was performed and in case of an own creative part (see below), which methods were used in addition.

## 3 Results

- Visualize the data first, show box plots, either the full data set **or** the samples of the group
- explain briefly what you see in the box plot
- Show the effect size (means of groups or differences between the means)
- perform an ANOVA:
  - the ANOVA
  - check variance homogeneity and approximate normality
  - perform a post-hoc test
- give a short explanation of the ANOVA results

**Creative part:** You can also be somewhat creative and analyse further properties of the data, e.g. length, width, weight, ... Select appropriate test methods, e.g. t-tests, ANOVA, correlation or regression, etc. You may also use **tidyverse** methods (e.g. `group_by` and `summarize`) to summarize the data (Wickham et al., 2019). It can also be possible to try a two-way ANOVA with a subset of the data. In that case, make sure to have a balanced data set or use `Anova` function (with capital letter “A”) from package **car**.

## 4 Discussion and Conclusions

The discussion should contain three parts:

1. The “scientific” toy problem: Summary of the outcome of the ANOVA experiment (focus on the fruits).
2. Technical aspects about the ANOVA or other methods:
  - do the results look plausible and sound? Can things be made better?
  - are there any comments to the method?
  - Which results were obtained from additional analyses from the creative part?
3. A conclusion, how can the results can be interpreted. Which clementines would you buy? Why?

## 5 Appendix

### 5.1 Hypotheses

It is important to formulate clear hypotheses. Here are a few **examples**, related to the data set from 2019. Please think about it and define your own hypotheses, related to the **current** data set.

- $H_{0,1}$ : The mean weight of the fruits is the same in all samples.
- $H_{A,1}$ : The weight is different in any of the samples.
- $H_{A,2}$ : Which brand is the smallest? The mean weight of smallest sample is significantly smaller than of the 2nd samplest sample.
- $H_{A,3}$ : The fruits from the premium brands are bigger than corresponding basic brands.

**Note:** Hypotheses  $H_{A,2}$  and  $H_{A,3}$  have their own, different  $H_0$ .

A hypothesis like  $H_{A,3}$  is more difficult and optional. It requires a two-way ANOVA and can only be applied to a subset of the data, where different brands from the same shops are available. Is a similar comparison possible for the 2022 data?

### 5.2 Measurement methods

- **Weight:** was determined with a kitchen scale in gramm (g).
- **Height and Width:** were measured with a **caliper** (Fig. 1)

Figure 1: Size measurement with a digital caliper.

### 5.3 R example code

- The following code is intended as a basic example only.
- It is recommended to adapt the script to analyse the data from the current year (2022).
- However, if you want to compare it with some of previous data, we are curious to see what you can make out of it.
- Don't forget that it is an exercise, not a serious analysis, so feel free to create your own story.
- Don't make your report too technical, concentrate on your message.
- If you like to share your code, put it in a separate file.

```
library(readxl)

brands <- read_excel("Clementines_2019.xlsx", "Brands")
fruits <- read_excel("Clementines_2019.xlsx", "Fruits")

dat <- left_join(fruits, brands) # merge tables by their common column 'Brand'
dat$brand <- factor(dat$brand)

boxplot(weight ~ brand, data=dat)

## the ANOVA
m <- lm(weight ~ brand, data=dat)
anova(m)

## posthoc test
TukeyHSD(aov(m))

## graphical display of Tukey's test
plot(TukeyHSD(aov(m)), las=1, cex.axis=0.5)

## graphical and numerical checks of variance homogeneity
plot(m, which=1)
fligner.test(weight ~ brand, data=dat)
```

```
## approximate normality of residuals
plot(m, which=2)

## optional: special one-way anova alternative if variances are unequal
oneway.test(weight ~ brand, data=dat)
```

## 5.4 Text processing

The report can be written in any text processing software, e.g. Microsoft Word, LibreOffice Write or Quarto. Quarto needs a little extra learning, but is an extremely efficient way to combine text and analysis with **R** in one document and write it directly in RStudio. A comprehensive documentation can be found on <https://quarto.org/>.

## 5.5 Questions and literature research

Please post questions and comments to the Matrix chat group or the Forum. Ideas are also welcome. As the exercise is a toy example, it may be difficult to find relevant citable literature. However, we don't limit creativity.
